## CLASS NOTES FOR CBSE

### Chapter 04. Animal Kingdom

#### 01. Basis of Classification

##### Level of body organization :

|                    |   |                                                                                                                                                  |
|--------------------|---|--------------------------------------------------------------------------------------------------------------------------------------------------|
| Protoplasmic level | → | In protozoans, acellular body performs all biological activities.                                                                                |
| ↓                  |   |                                                                                                                                                  |
| Cellular level     | → | In sponges, cells are arranged as loose cell aggregates and division of labour occurs among cells (Tissues absent).                              |
| ↓                  |   |                                                                                                                                                  |
| Tissue level       | → | In coelenterates and ctenophores, cells performing the same function are arranged into tissues.                                                  |
| ↓                  |   |                                                                                                                                                  |
| Organ level        | → | In platyhelminthes and other higher phyla tissues are grouped together to form organs.                                                           |
| ↓                  |   |                                                                                                                                                  |
| Organ system level | → | In higher animals, organs further organise to form organ systems e.g. Aschelminthes, Annelida, Arthropoda, Mollusca, Echinodermata and Chordata. |

##### Symmetry:

- 1) **Asymmetry** :- When any plane that passes through the centre does not divide the body of animals into two equal halves.  
e.g. : most of sponges are asymmetric.
- 2) **Radial symmetry** : When any plane passing through the central axis of the body divide the animal into two identical halves.  
e.g. : Coelenterates, ctenophores and echinoderms (adult)
- 3) **Billateral symmetry** : When the body can be divided into identical left & right halves in only one plane.  
e.g. : Platyhelminthes to chordates.

##### Germinal layers :-

- (a) **Diploblastic** : Animals in which the cells are arranged in two embryonic layers ectoderm and endo-derm with an intervening undifferentiated mesoglea e.g. Sponges, Coelenterates and Ctenophores.
- (b) **Triploblastic** : Those animals in which the developing embryo has a third germinal layers Mesoderm in between the ectoderm and endoderm e.g. Platyhelminthes to chordates.

**Body Cavity or Coelom :**

Presence or absence of a cavity between the body wall and gut wall is very important in classification.

- (a) **Acoelomates** : Animals in which the body cavity is absent  
e.g. Platyhelminthes
- (b) **Pseudocoelomates** : Animals in which body cavity is not lined by mesoderm, instead, the mesoderm is present as scattered pouches in between the ectoderm and endoderm. Such a body cavity is called pseudocoelom.  
e.g. Aschelminthes.
- (c) **Coelomates** : Animals possessing coelom i.e. the body cavity which is lined by mesoderm on all sides  
On the basis of embryonic development, the coelom is of two types.
  - (i) **Schizocoel** : Coelom formed by splitting of a mesodermal mass  
e.g. Annelida, Arthropoda, Mollusca.
  - (ii) **Enterocoel** : Coelom formed by fusion of gut pouches during embryonic stage  
e.g. Echinodermata, Hemichordata and Chordata.

**Body plan :**

- (a) **Cell-aggregate type** : e.g. Sponges
- (b) **Bling Sac type** : Animals in which digestive system is incomplete, it has only single opening to the outside of the body that serves as both mouth and anus.  
e.g. Coelenterates to Platyhelminthes
- (c) **Tube-within-tube type** : Found in those animals having complete digestive tract i.e. with separate openings mouth and anus.  
e.g. Nematelminthes to chordates

**Segmentation :**

- (a) **Pseudometameric** : e.g. Tapeworms
- (b) **Metameric** : In Annelids, arthropods and chordates.  
In these animals, the body is externally and internally divided into segments with a serial repetition of atleast some organs, this is called metameric segmentation and the phenomenon is known as Metamerism.

**Notochord :**

It is a mesodermally derived rod-like structure formed on the dorsal side during embryonic development in some animals.

- (a) **Non-chordates** : Animals without notochord e.g. Porifera to hemichordata
- (b) **Chordates** : Animals with notochord.

**Circulatory system :**

- (a) **Open type** : In which the blood remains filled in tissue spaces due to absence of blood capillaries. e.g. Arthropods, Molluscs, Echinoderms, Hemichordates and some lower chordates like tunicates.
- (b) **Closed type** : In which the blood is circulated through a series of vessels of varying diameters i.e. arteries, veins and blood capillaries  
e.g. Annelids, Cephalopod molluscs, Vertebrates etc.

**Embryonic development :**

On the basis of fate of blastopore, animals can be divided into two categories :

- (a) **Protostomiate** : Animals in which mouth is formed first (Blastopore → Mouth)  
e.g. Platyhelminthes to Mollusca
- (b) **Deuterostomiate** : Animals in which anus is formed earlier than mouth (Blastopore → Anus)  
e.g. Echinoderms, Hemichordates and Chordates.
